UMD DATA605 - Big Data Systems Orchestration with Airflow Deploying an Application

Dr. GP Saggese

gsaggese@umd.edu

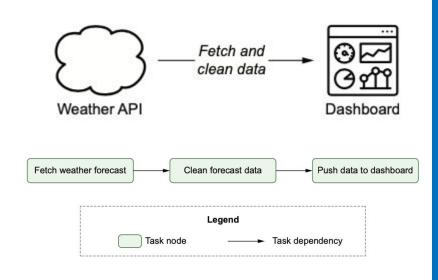

Orchestration - Resources

- Concepts in the slides
- Airflow tutorial
- Class project
- Web resources
 - Documentation
 - Tutorial
- Mastery
 - Data Pipelines with Apache Airflow

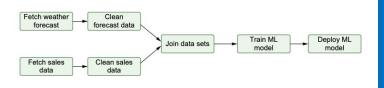

Workflow Managers

- Orchestration problem = data pipelines require to coordinate jobs across systems
 - Tasks run on a certain schedule
 - Tasks need to be executed in a specific order
 - Notify if a job fails
 - Retry on failure
 - Monitor: track how long it takes to run
- E.g., live weather dashboard
 - Fetch the weather data from API
 - Clean / transform the data
 - Push data to the dashboard / website

Workflow Managers

- Workflow managers address the orchestration problem
 - E.g., Airflow, Luigi, Metaflow, make, cron ...
- Represent data pipelines as DAGs
 - Nodes are tasks
 - Direct edges are dependencies
 - A task is executed only when all the ancestors have been executed
 - Independent tasks can be executed in parallel
 - Re-run failed tasks incrementally
- How to describe data pipelines
 - Static files (e.g., XML, YAML)
 - Workflows-as-code (e.g., Airflow and Python)
- Provide scheduling
 - How to describe what and when to run
- Provide backfilling and catch-up
 - Horizontally scalable (e.g., multiple runners)
- Provide monitoring web interfaces

(Apache) Airflow

- Developed at AirBnB in 2015
 - Open-sourced as part of Apache
- Batch oriented framework for building data pipelines

- Represented as DAGs
- Described as code in Python
- Scheduler with rich semantics
- Web-interface for monitoring
- Large ecosystem
 - Support many DBs
 - Many actions (e.g., emails, pages)
- Hosted and managed solution (e.g., AWS)
 - You will run Airflow on your laptop in class project

Airflow: Execution Semantics

Scheduling semantic

- Describe when the next scheduling interval is
- Similar to `cron`

Retry

 If a task fails, it can be re-run (after a wait time) to recover from intermittent failures

Incremental processing

- Time is divided in intervals given the schedule
- Execute DAG for data only in that interval, instead of processing the entire data set

Backfilling

- Execute DAG for historical schedule intervals that occurred in the past
- E.g., if the data pipeline has changed one needs to re-process data from scratch

Airflow: What Doesn't Do Well

Not great for streaming pipelines

- Better for recurring or batch-oriented tasks
 - E.g., schedule every hour (instead of process data as it comes)

Prefer static pipelines

 DAGs should not change (too much) between runs

No data lineage

- No tracking of how data is transformed through the pipeline
- Need to be implemented manually

No data versioning

- No tracking of updates to the data
- Need to be implemented manually

Airflow: Components

Users

Web-server

- Visualize DAGs
- Monitor DAG runs and results

Scheduler

- Parse DAGs
- Keep track of dependencies completed
- Add tasks to the execution queue
- Schedule tasks when time comes

Metastore

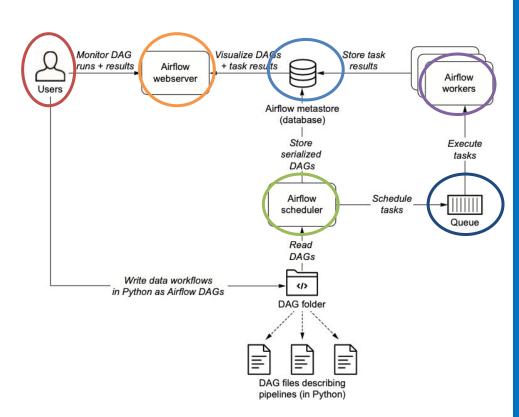

- Keep the state of the system
- E.g., what nodes have been executed

Queue

- Tasks queued up for execution when ready
- Tasks picked up by a pool of Airflow workers

Workers

- Pick up tasks from Queue
- Execute the tasks
- Register their outcome in Metastore

- From the <u>tutorial</u> for Airflow 2.2.2
- Follow <u>README</u> in https://github.com/sorrentum/sorrentum/tree /master/sorrentum_sandbox

- The script describes the DAG structure as Python code
 - There is no computation inside the DAG code
- The Scheduler executes the code to build DAG
- BashOperator creates a task wrapping a Bash command

airflow/example_dags/tutorial.py from datetime import datetime, timedelta from textwrap import dedent # The DAG object; we'll need this to instantiate a DAG from airflow import DAG # Operators; we need this to operate! from airflow.operators.bash import BashOperator

- Dict with various default params to pass to the DAG constructor
 - Can have different set-ups for dev vs prod
- Instantiate the DAG

```
airflow/example_dags/tutorial.py
                                                                                              view source
# These args will get passed on to each operator
# You can override them on a per-task basis during operator initialization
default_args = {
    'owner': 'airflow',
    'depends_on_past': False,
    'email': ['airflow@example.com'],
    'email_on_failure': False,
    'email_on_retry': False.
    'retries': 1,
    'retry_delay': timedelta(minutes=5),
    # 'queue': 'bash_queue',
    # 'pool': 'backfill',
    # 'priority_weight': 10,
    # 'end_date': datetime(2016, 1, 1),
    # 'wait_for_downstream': False,
    # 'dag': dag,
    # 'sla': timedelta(hours=2),
    # 'execution_timeout': timedelta(seconds=300),
    # 'on_failure_callback': some_function.
    # 'on_success_callback': some_other_function,
    # 'on_retry_callback': another_function,
    # 'sla_miss_callback': yet_another_function,
    # 'trigger_rule': 'all_success'
```

```
airflow/example_dags/tutorial.py

with DAG(
   'tutorial',
   default_args=default_args,
   description='A simple tutorial DAG',
   schedule_interval=timedelta(days=1),
   start_date=datetime(2021, 1, 1),
   catchup=False,
   tags=['example'],
) as dag:
```

- DAG defines tasks by instantiating
 Operator objects
 - The default params are passed to all the tasks
 - Can be overridden explicitly
- One can use a Jinja template

```
airflow/example_dags/tutorial.py

t1 = BashOperator(
   task_id='print_date',
   bash_command='date',
)

t2 = BashOperator(
   task_id='sleep',
   depends_on_past=False,
   bash_command='sleep 5',
   retries=3,
)
```

```
airflow/example_dags/tutorial.py

templated_command = dedent(
    """

{% for i in range(5) %}
    echo "{{ ds }}"
    echo "{{ macros.ds_add(ds, 7)}}"
    echo "{{ params.my_param }}"

{% endfor %}

"""

)

t3 = BashOperator(
    task_id='templated',
    depends_on_past=False,
    bash_command=templated_command,
    params={'my_param': 'Parameter I passed in'},
)
```

Add tasks to the DAG

```
t1 >> [t2, t3]
```

Airflow: Concepts

- Each DAG run represents a data interval, i.e., an interval between two times
 - E.g., A DAG scheduled @daily, each data interval starts at midnight for each day, ends at midnight of next day
- Logical date
 - Simulate the scheduler running DAG / task for a specific date
 - Even if it is physically run now
- DAG scheduled after data interval has ended
